This document introduces the Simple-Pair technology developed by Espressif. The document focuses on Simple-Pair features, their uses and the demo code.

The structure is as below:

<table>
<thead>
<tr>
<th>Chapter</th>
<th>Title</th>
<th>Subject</th>
</tr>
</thead>
<tbody>
<tr>

1. Simple-Pair Introduction

Based on ESP IE, Simple-Pair is used for fast negotiation or exchange of Key (or other information) between two devices.

Simple-Pair enables Key exchange in only a few steps. For the time being, Simple-Pair supports Key exchange between Station and AP with the Key being limited to 16 bytes. The Key is eventually sent from AP to Station. Simple-Pair contains a Key named TempKey which ensures the final exchange step. TempKey is stored at the Station end and should be acknowledged by the Station and the AP before Simple-Pair is initialized.

Simple Pair is designed for fast exchange of Key and for realizing pairing between two devices that have never been paired before. It is recommended to disable the paired devices' sleep mode temporarily in case of packet transmission failure. The key to be exchanged is initially stored at the AP end and is then sent from AP to Station, at which point Simple-Pair between the devices is completed. However, for the application layer, pairing is finished only after trial, when the Key is verified as valid.

📖 Note:

*Smart phones can be used during Simple-Pair. Chapter 3 provides an example.*
2. Simple-Pair User Guide

There are basically only three steps for Simple-Pair: Set Peer Info, AP ANNOUNCE (STA SCAN) and START Negotiate. All statuses are indicated by the callback function.

Users need to register the status callback function to indicate a status during Simple-Pair, such as pairing-completed status, negotiation request, timeout, error, etc. For example, the status callback function indicates a negotiation request from the Station, so that the AP can decide whether or not to accept it. If the status callback function returns a wrong value, then some action has to be taken according to the value (for details, please see SDK_V2.0 Simple Pair Demo).

The AP needs to enable the Simple-Pair Announce mode and the Station needs to enable the Simple-Pair Scan mode before activating Simple-Pair. Then, the Station will send IEEE802.11 Probe Request to AP, i.e., scan APs, so that both the Station and the AP would know which is ready for Simple-Pair.

The Station will select the AP that is ready for Simple-Pair from BSS_INFO, set the MAC address and TempKey of the AP, then send STA Negotiate Start.

Upon receiving the request, the AP itself, or with the help of a smart phone, will decide whether or not to accept the request. If the request is accepted, the AP will set the MAC address, TempKey and the exchange Key of the Station, and then will send AP Negotiate Start; otherwise, the AP will send AP Negotiate Refuse.

If the Station receives AP Negotiate Start, negotiation will start; if the Station receives AP Negotiate Refuse, it will inform the application layer through the status callback function and the latter will respond accordingly.

After negotiation, the Station will get the exchange Key from the AP, which means Simple-Pair is completed. The application layer needs to make sure the Key is correct through verification.

⚠ Notice:

Before negotiation, the application layer needs to make sure no MAC address has been set to a Key by ESP-NOW (or by any other function that may be developed in the future). If there is, please delete the function; otherwise, wrong Key may be used in Simple-Pair.
The following is an example of exchanging ESP-NOW's key via Simple-Pair.

**Note:**
Besides exchanging ESP-NOW’s Key, Simple-Pair can also be used to exchange other function’s Key.

After Simple-Pair is finished, please verify the Key exchanged. A smart phone can control part of the process. If Simple-Pair is successful, the user can decide if the SLAVE pairs with another CONTROLLER or not.
